

Q1: Document the process of how you use Git workflows to collaborate with your team members.

A1: The process of Git workflows to collaborate with team members works as follows. Git commit is used to commit changes, and these changes can be pushed to the repository using git push. This ensures any changes made on one user's machine reflect in the repository so that other members can see the changes. To stay updated with the latest version, team members pull changes using git pull. Code is reviewed through pull requests before merging with a git merge. This is to ensure no branches conflict, which happens when two different copies of the same branch exist and thus cannot be simply merged back into origin without any resolving.
